

5 Facts You Need to Know About Multiple Sclerosis

by ABIGAIL BUDD

Multiple Sclerosis Facts

My friend's son was recently diagnosed with relapsing and remitting multiple sclerosis (MS) at the age of 12. This is devastating news for anyone, but for a child that young, it must be frightening and bewildering. So, I offered my support to my friend, as let's face it, I'm a reluctant expert in all things multiple sclerosis. How do you condense 11 years of experience into a few easy to digest facts though? How do I impart all my observations, musings and discoveries about living with MS onto someone else? This got me thinking about some multiple sclerosis facts, and which are most useful to the newly diagnosed and the seasoned professionals like me!

5 Facts About Multiple Sclerosis

Here is my list of facts about MS you should be aware of.

1. Everyone's Journey is Different

This is important to remember, especially when my friend looks at me on my mobility scooter and thinks about her beautiful boy. Just because one person has physical disabilities associated with MS doesn't mean everyone will end up with the same issues.

I have a friend with MS who can still walk normally after living with MS for 20 years. You might be forgiven for looking at her and thinking my MS is worse than hers, but this isn't necessarily the case. She's been unable to work for years due to crippling fatigue, and her cognitive function is much worse. Compared to me, I don't suffer from fatigue, and my cognitive function isn't as impacted.

Comparing yourself to other people with MS is never a good idea as the disease can progress differently, and we all experience symptoms individually.

2. The Cause is Unknown

I've written about this a lot over the years and have thought a lot about it too. Was it something I did in my 20s that led to my diagnosis in my 30s? Did I cause it to happen, or was it due to a random set of unlucky occurrences?

The truth is doctors don't know why the body attacks myelin in people with MS. However, they do believe some factors may increase the risk of developing it.

- **Smoking.** I tick this box as I was smoking a pack a day in my 20s.
- **Family history.** Relatives with MS or other autoimmune diseases can increase the risk.
- **Being Caucasian.** Particularly of Northern European descent have a higher risk.
- **Living in a temperate climate.** Areas with this type of climate can increase symptoms and make them

worse.

Environmental and personal factors likely play a part in developing MS too. However, people of different ethnic backgrounds, who live in hot countries and who have never smoked can also get MS. These MS causes are confusing, but it is unlikely to be anything you have done.

3. It's More Prominent in Females

Over 2 million people worldwide have MS, and out of those people, two-thirds are women. No one knows the reason for this, but hormones may play a part.

4. There's No Cure

Although there are lots of options available to treat MS symptoms, and disease-modifying therapies (DMTs) can slow down the progression and prevent relapses, there is no cure for MS. It's a disease we must learn to live with and come to terms with.

Work is ongoing though, looking at stem cell treatments and other research, so some neurologists believe a cure is possible in the future. Procedures to repair myelin damage are also being researched, so if a cure isn't found, then more effective treatments may be possible if we are patient!

5. MS Isn't a Terminal Illness

It upsets me a lot when I hear stories in the media, describing people dying of MS. You don't die of it, but you do die with it.

For someone with a terminal illness, death is expected within weeks or months, and there is no possibility of recovery. MS is not a terminal illness, but it is a life-long condition, and most people can expect to live with it for 40 or 50 years.

Most people with MS will live to their mid-70s, so there is a reduction in life expectancy of six to seven years compared to the general population. People who go on to develop severe MS may get more infections or develop additional health conditions more easily than other people. Eventually, they may go on to die from these.

This highlights the need for people with MS to look after themselves more than the average person. We need to eat well, get plenty of rest and take regular exercise to give ourselves the best chance.

In Conclusion

I try and stay positive and don't let MS get me down, but I would still much rather not be living with it! I would much rather know nothing about these MS facts and be unable to support my friend and her son.

I think the most important fact of all is that no two people with MS are the same. We need to navigate ourselves through it and get to know our own MS to give ourselves the best chance of winning!
